## Abstract

Objective: In this study our main aim is to assess the incidence of heart diseases in hypertension of hypertensive patients in Bangladesh. Method: This cross-sectional study was conducted at NICVD, Dhaka from October 2010 to September 2011 where 150 rural and urban individuals (age $\geq 21$ years) were evaluated and all data was recorded methodically in a preformed data sheet and was analyzed by relevant statistical procedures. Result: in the study male patients were $18.1 \%$ higher than female. Out of 150 patients 99 male and 64 female belongs to hypertension group. Conclusion: we can conclude that in Bangladesh patients with hypertension is prone to have heart diseases. More studies are suggestive to estimate the incidence of hypertension in heart diseases.
Keywords: Cardiovascular disease (CVD), hypertension, high blood pressure.

## Introduction

Hypertension (HTN or HT), also recognized as high blood pressure (HBP), which is a long-term medical disorder in which the blood pressure in the arteries is persistently elevated. High blood pressure typically does not cause symptoms. High blood pressure is classified as either primary (essential) high blood pressure or secondary high blood pressure. Around $90-$ $95 \%$ of cases are primary, defined as high blood pressure due to nonspecific lifestyle and genetic factors. Lifestyle factors that intensification the risk include excess salt in the diet, excess body weight, smoking, and alcohol use. The remaining 5$10 \%$ of cases are categorized as secondary high blood pressure, defined as high blood pressure due to an identifiable cause, such as chronic kidney disease, narrowing of the kidney arteries, an endocrine disorder, NSAID, steroid or the use of birth control pills [1, 2].

Blood pressure is stated by two measurements, the systolic and diastolic pressures, which are the maximum and minimum pressures, respectively. For
most adults, normal blood pressure at rest is within the range of $100-130$ millimeters mercury ( mmHg ) systolic and $60-80 \mathrm{mmHg}$ diastolic. For most adults, high blood pressure is present if the resting blood pressure is persistently at or above $140 / 90 \mathrm{mmHg}$.

Ambulatory blood pressure one to care over a 24 -hour period appears more exact than officebased blood pressure measurement [2].

Hypertension is the top risk factor for death and disability internationally and disproportionately impacts low-and middle-income countries (LMICs), where more than two-thirds of people with hypertension live. Hypertension is the main cause for more than half of the cardiovascular diseases (CVD), stroke and heart failure and is a foremost risk factor for fetal and maternal deaths in pregnancy, dementia and renal failure. The occurrence of hypertension is growing worldwide and is predicted to affect more than 500 million people by 2025 [3].

Fig-1: The progression from lifestyle changes to the incidence of hypertension and cardiovascular disease (CVD). CHD indicates coronary heart disease by scheme presentation [4]

Hypertension is a substantial community health challenge and has a main impact on healthcare costs, contributing to around $10 \%$ of total healthcare spending internationally. Hypertension imposes a thoughtful economic burden on individuals, households, healthcare systems and the entire state. In current years, hypertension and CVDs have increased in South-East Asia including Bangladesh as a result of rapid urbanization, increased life expectancy, unhealthy diet, and lifestyle fluctuations [3, 5]. In this study our main objective is to discover the incidence of heart diseases in hypertension of hypertensive patients in Bangladesh.

## Objective

General Objective: To evaluate the incidence of heart diseases in hypertension of hypertensive patients in Bangladesh.

## Specific Objective

- To detect frequency of hypertension and nonhypertensive in the patients
- To estimate incidence of systolic and diastolic hypertension of all study patients.

## Methodology

Study type: This was a cross sectional study.
Study Place and Period: This study was conducted from October 2010 to September 2011in NICVD, Dhaka

## Method

A random sample of 150 rural and urban individual (age $\geq 21$ years) were included in a crosssectional study. All male and female $\geq 20$ years of age were considered eligible except pregnant women and subjects on medication. The eligible participants were informed about the objectives of the study. Each participant's was interviewed for the status of physical activities, family history of hypertension, diabetes, smoking, annual income etc were collected using
modified WHO-STEPS protocol. Diagnosis of hypertension (WHO criteria): Grade 1 (mild) $=140-$ $159 / 90-99 \mathrm{~mm}$ of Hg , Grade 2 (moderate) $=160-179 /$ $100-109 \mathrm{~mm}$ of Hg , Grade 3 (severe) $=\geq 180 / \geq 110$ mm of Hg .

## Statistical Analysis

All data was recorded methodically in a preformed data sheet and was analyzed by relevant statistical procedures with the windows software version 12.0. The prevalence rates of hypertension were determined by simple percentage. Unpaired t-test, chisquare tests were done to see the level of significance. All associations were tested by co-relation coefficient (r). Binary logistic regression was used to quantify the individual risk prediction of hypertension with different independent risk factors. All statistical test were considered significant at the level of $95 \%$ ( $\mathrm{p}<0.05$ ).

## Results

In Table-1 shows age distribution of the patients where for both male and female, most of the patients belongs to (41-50) age group. The following figure is given below in detail:

Table-1: Age distribution of the patients

| Age group | Male, \% | Female, \% |
| :--- | :--- | :--- |
| $21-30$ | $5 \%$ | $4.8 \%$ |
| $31-40$ | $9 \%$ | $8.2 \%$ |
| $41-50$ | $57 \%$ | $53 \%$ |
| $51-60$ | 20 | 21 |
| $61-70$ | $11 \%$ | $13 \%$ |

In Figure-2 shows gender distribution of the patients where among 150 patents male patients were $18.1 \%$ higher than female. The following figure is given below in detail:

Fig-2: Gender distribution of the patients
In Figure-3 shows the frequency of hypertension and non-hypertension in the patients where out of 150 patients 99 male and 64 female belongs to hypertension group. The following figure is given below in detail:

Fig-3: The frequency of hypertension and non-hypertension in the patients

In Table-2 shows the incidence of systolic and diastolic hypertension of all study patients, where among total 53patients, systolic hypertension were $25.81 \%$ whereas diastolic hypertension $30.61 \%$. The following table is given below in detail:

Table-2: The incidence of systolic and diastolic hypertension of all study patients

| Group | $\%$ |
| :--- | :--- |
| Systolic hypertension | $25.82 \%$ |
| Non systolic hypertension | $74.0 \%$ |
| Total | $100 \%$ |
| Diastolic hypertension | $30.61 \%$. |
| Non diastolic hypertension | $69.3 \%$ |
| Total | $100 \%$ |

In Figure-4 shows distribution of patients according their living place where $51 \%$ people lived in rural area where as $49 \%$ people in urban area. The following figure is given below in detail:

Fig-4: Distribution of patients according their living place
In Table-3 shows Correlation of hypertension with family history, smoking, occupation, physical activity, annual income, obesity, BMI, Gender, heart diseases and age in patients where we found that mostly age and heart diseases strongly correlated with hypertension than other variable. The following table is given below in detail:

Table-3: Correlation of hypertension with family history, smoking, occupation, physical activity, annual income, obesity, BMI, Gender, heart diseases and age in patients

| Correlation of hypertension with | r-value | p-value |
| :--- | :--- | :--- |
| Family history | -.228 | $<0.01$ |
| Smoking | -.126 | $<0.01$ |
| Income | -.131 | $<0.01$ |
| Occupation | .009 | $>0.05$ |
| Physical activity | -.141 | $<0.01$ |
| Obesity | -.284 | $<0.01$ |
| BMI | .276 | $<0.01$ |
| Gender | -.023 | $>0.05$ |
| Age | -.286 | $<0.01$ |
| Heart diseases | -.287 | $<0.01$ |

## DISCuSSION

In this cross-sectional study, our goal was to discover the incidence of heart diseases in hypertension of hypertensive patients in Bangladesh. Hypertension, is the strongest risk factor for cardiovascular disease (CVD) or heart diseases.

In our study, the blood pressure was measured in all study patients where we found that the blood pressure was statistically significantly higher in hypertension as compared with non-hypertensive. During the study we noted that the prevalence of hypertension observed in this study was higher than the previous study [6].

Hypertension is a major public health issue in Bangladesh, India and in other developing countries Countries with an ageing population will be expected to have a higher prevalence of hypertension than developing countries with a younger population's such as Bangladesh, India, but there are studies, which have
documented in developing countries, a high prevalence rate of hypertension [7, 8]. Our study also showed that with the increasing age gradually more subject with hypertension and that was similar with other finding [9].

In this study we detected that the frequency of hypertension in male was 99 and in female was 64respectively. Though the prevalence rate was higher in male but there was no statistically significant difference between male and female. Our study showed that the hypertension prevalence was high among people with high obesity. The similar finding also observed in different studies done in different rural area of India. In this study we also observed that high prevalence of hypertension of patients with positive heart diseases and also hypertension heart diseases strongly correlated with each other, where different study supported our observation. In this study we also observed that high prevalence of hypertension of patients with positive heart diseases and heart diseases and hypertension strongly correlated with each other, where different study supported our observation.

During the study where among total 150 patients, we found that systolic hypertension was $25.81 \%$ whereas diastolic hypertension $30.61 \%$. But one study reported that MI patients were more affected by high systolic blood pressure than diastolic blood pressure. It might be due to injury of endothelium by systolic blood pressure and thereby enhanced atherosclerosis. Elevated serum triglycerides, total cholesterol, and LDL had been well-established risk factors of cardiovascular disease.

Another study reported that extra salt intake along with age, BMI, physical inactivity, tobacco use and family history of stroke/CVD was found to have significant relationship with hypertension and prehypertension [5]. Also, more than 35 million people in coastal Bangladesh are vulnerable to increasing freshwater salinization; elevated salinity in drinking water has been found to be associated with higher BP in young coastal populations. During the study we also found positive correlation with this report because in the study that most the patients from rural area, so they might unaware threatful effect of salinity in drinking water. The overall risk perception regarding excessive salt consumption is low and there is widespread belief that the cooking process can render the salt harmless. High salt intake presumably contributes to hypertension, which is an established risk factor for CAD [10, 11].

## Conclusion

After several outcome, we can conclude that in Bangladesh patients with hypertension is prone to have heart diseases. More studies are suggestive to estimate the incidence of hypertension in heart diseases.
