Abstract

The present study was undertaken to assess the effects of pranayama on pulmonary functions. Sixty healthy young female subjects (age group 18-28 years) were selected. They have to do the selected pranayama practices daily for about half an hour. The observations were recorded by MEDSPIROR, in the form of FVC, FEV₁ and PEFR on day-1, after 4 weeks and 8 weeks of their pranayama practice. There was a significant increase in FVC, FEV₁ and PEFR at the end of 8 weeks.

Keywords: Pranayama FVC, FEV₁, PEFR.

INTRODUCTION

Medical science tries to achieve an optimum physical and mental health of the individual through preventive, curative and promotive aspects. However, for a long time medical professionals have laid much emphasis on the curative aspect and only relatively recently the preventive aspect is also being emphasized. In yogic practice the stress is mainly on the preventive aspect, although some yogic methods are also prescribed for curative purpose as well.

A number of studies have been alone to assess the effect of pranayama on pulmonary functions. Udupa et al., studied the effects of some breathing exercises (pranayama) in normal subject [1]. Nayar et al., documented the effect of yogic exercises on human physical efficiency [2]. Yadav Raj Kumar et al studied the effect of yogic practice on pulmonary functions in young females [3]. In another study by Miles Wales, oxygen consumption during three yoga-breathing patterns were studied [4]. In a related work, Makwana et al., also studied the effect of short term yoga practice on pulmonary function tests [5].

The present study has been done exclusively on young healthy females to add more data in the field of yoga and pulmonary functions.

METHODS

The study was carried out at the Yoga Therapy and Research Centre (YOGA O.P.D) Department of physiology, SMS hospital, Jaipur.
Day-1 means the very first day the subjects started yogic practice. For PFT, the subjects were first explained the whole procedure and were demonstrated the same after obtaining their consent, the subjects performed the test in sitting position.

**Statistical Analysis**

The results of PFT are presented as Mean±S.D. The data were analyzed using students’ t test. P values<0.05 were considered significant.

**Results**

The results have been summarized in Table-1. The FVC, FEV-1, and PEF of all the subjects on day-1, 4 weeks and 8 weeks has been given. It is evident that the PFT parameters have higher values at 4 weeks and 8 weeks in comparison to day-1 values. The P value has been calculated at 4 weeks and 8 weeks in comparison to values on day-1.

**Discussion**

In our study, FVC and FEV-1 were significantly higher at 4 weeks and 8 weeks from day-1 (P<0.001). However, PEF was not statistically significant at 4 weeks but value of PEF is higher at 4 weeks in comparison to day-1. At 8 weeks, PEF is significantly higher than day-1 (P<0.05).

Yadav Raj Kumar et al., reported significant increase in FVC, FEV-1 and PEF after 12 weeks of Yoga training [3].

Makwana et al., reported significant increase in FVC following 10 weeks of yoga training [5] others have recorded similar observations [2, 6]. The improvement in vital capacity is due in part to increase in development of respiratory musculature incidental to regular practice of yogic exercises [7].

By the yogic practice the respiratory apparatus is emptied and filled more completely and efficiently which is recorded in terms of increased FVC. Similar ventilatory training even in elderly subjects (age 60 to75 yrs) has been shown to improve lung volumes and capacities [8]. Joshi et al., reported significant increase in FVC and PEF following 6 weeks of pranayama practice [9].

Lung inflation near to total lung capacity is a major physiological stimulus for the release of lung surfactant [10] and prostaglandins into alveolar spaces [11], which increase lung compliance and decrease bronchial smooth muscle tone respectively. The other possible mechanism for improved PFT may be:

1. Cleansing procedures cleans the infective nasal secretion.
2. Increased power of respiratory muscles that is due to the work hypertrophy of the muscles during pranayama and other exercises.
3. Yogic breathing exercises train practitioners to use the diaphragmatic and abdominal muscles more efficiently thereby emptying and filling the respiratory apparatus more efficiently and completely [5]
4. Yoga, with its calming effect on the mind can reduce and release emotional stresses, thereby with drawing the broncho-constrictor effect.

Thus, practice of yogic exercises seems to be beneficial for respiratory efficiency. A number of studies have been done to show the beneficial effects of yoga on asthmatic patients [12, 13].

Bera et al., have studied recovery from stress by yogic relaxation posture in their work [14].

In conclusion, it can be stated that pranayama is beneficial for the better maintenance of body functions, particularly pulmonary functions, even in normal healthy persons with significant increase in FVC, FEV-1 and PEF at the end of 8 weeks of pranayama practice in young healthy females.
